PHOTOGRAPHIC SOLID FINE-GRAIN DISPERSION,
METHOD FOR PREPARING THE SAME, AND SILVER HALIDE
PHOTOGRAPHIC LIGHT-SENSITIVE MATERIAL

5 FIELD OF THE INVENTION

The present invention relates to a solid fine-grain dispersion of a water-insoluble photographically useful compound, and to a method for preparing the same, and further to a silver halide photographic light-sensitive material using the same.

BACKGROUND OF THE INVENTION

Examples of a water-insoluble photographically useful compound include a dye image-forming coupler, a dye image-providing redox compound, an antistain agent, an antifoggant, an ultraviolet absorber, an antifading agent, a color-mix-preventing agent, a nucleating agent, a silver halide solvent, a bleach-accelerator, a developing agent, a filter dye and a precursor thereof, a dyestuff, a pigment, a sensitizing agent, a hardener, a whitening agent, a desensitizing agent, an antistatic agent, an antioxidant, a developer scavenger, a mordant, a matte (matting) agent, a development accelerator, a development inhibitor, a heat solvent, a color-tone modifier, a sliding (slipping) agent, and a polymer latex for

dispersion that is used as a medium for dispersing these compounds, and a water-insoluble inorganic salt (e.g. zinc hydroxide). These water-insoluble photographically useful compounds are used in a photographic emulsion layer or
5 another layer, as an aqueous dispersion or hydrophilic colloid dispersion of a solid fine-grain dispersion thereof. The above-described water-insoluble photographically useful compounds are described in, for example, Research Disclosure (R.D.) No. 17643, *ibid.* No.
10 18716, and *ibid.* No. 307105. As an example of these materials, a solid fine-grain dispersion of dyestuff is often used in a photographic emulsion layer or another layer for coloration, in order to absorb light in a specific wavelength region, and to thereby improve color
15 reproduction and sharpness, etc. Such a colored layer is called a filter layer, an antihalation layer, a crossover-cut filter layer, or so on, depending on its purpose. Further, photographic emulsion layers have been colored in order to prevent irradiation. It is necessary for these
20 solid fine-grain dispersions to be held (fixed) in an intended layer of the photographic coating membrane, and further for them to be sufficiently fine to the thickness of the layer.

Such a solid fine-grain dispersion of the
25 photographically useful compound can be prepared by an

ordinary method. Details of the method are described in, for example, "Kinosei Ganryo Oyo Gijutsu (Applied Technology of Functional Dyes), published by C. M. C. (1991).

5 The media dispersion method is one of ordinary methods. According to the method, a powder of a dye or a dye wetted with water or an organic solvent, which is called a wet cake, is mixed with a solvent to make a slurry, and then the resultant mixture is mechanically
10 pulverized (ground) in the presence of dispersion media (e.g. steel balls, ceramic balls, glass beads, alumina beads, zirconia silicate beads, zirconia beads, Ottawa sand), using a known pulverizer (e.g. a ball mill, a vibration ball mill, a planetary ball mill, an agitation
15 ball mill, an annular-type ball mill, a vertical sand mill, a roller mill, a pin-type mill, a spike mill, a co-ball mill, a caddy mill, a horizontal sand mill, an attritor).

 These dispersing tools are described in, for example, "Kagaku Kogaku Binran (Handbook of Chemical Engineering),"
20 published by Maruzen, Revised 5th edition.

 Of these media dispersion methods, the most generally used method for preparing fine grains of a photographically useful compound comprises the steps of:
 successively bringing (introducing) a slurry of the
25 compound in a milling (grinding) chamber of a dispersing

machine, which chamber is filled with media,

allowing the compound to contact with the media in the grinding chamber, thereby finely pulverizing the compound, and then

5 separating the media from the fine-grained compound by means of a screen, a gap, a slit, a mesh, or the like. This method is excellent in such points as productivity, wide usability, attainability of small grain size of the dispersed grains, and simplicity of a manufacturing
10 process.

However, in this method, there are such problems as that, because mechanical energy is used, the energy required to pulverize a material is large; that only a part of the applied energy is used for pulverization, and
15 the rest, which is the majority, is given off as thermal energy; that, because machine parts and media collide with each other, thereby causing abrasion, the resultant abrasion materials get mixed in the completed dispersion, which results in deterioration of property; that, because
20 the grain size distribution of the dispersion is wide, coarse grains are likely to remain; and that, if the supplied energy is increased so as to rapidly progress pulverization and to obtain fine grains, not only the above-described generation of heat and abrasion increase,
25 but also mixing in of a large amount of abrasion materials

takes place.

In particular, a dispersion of a photographically useful compound is coated on a support (base) as an extremely thin colloid layer. Recently, a tendency to
5 make a thin layer and high-speed coating of the colloid layer is increasingly progressing. In this case, such problems (defects) as pin holes and unevenness due to abrasion materials that will get mixed in a colloid layer, are actualized.

10 Media that have been used include, for example, steel balls, Ottawa sand, glass beads, dealkali glass beads, alumina beads, zircon beads, zirconia beads, and so on. Further, the grain size thereof has been generally 0.4 mm or more.

15 Of these media, it is known that steel balls cause metallic abrasion materials that result in defects when a dispersion is coated on a film, and they also cause coloring and an unpreferable chemical reaction. Ottawa sand, glass beads, and dealkali beads each have not only a
20 defect due to dispersed abrasion material but also a possibility that an alkali component or a metal salt resulting from the abrasion, decomposes or aggregates a dispersion. On the other hand, alumina beads, zircon beads, and zirconia beads are hard, and each has a high
25 bulk density, so that a great amount of energy can be

applied to the dispersion, which results in a high dispersion efficiency. However, because the machine parts of the dispersing machine are worn out, abrasion-resistant ceramic or polymeric materials have been used as a material of the machine part.

However, recently such needs as improvement of the dispersion efficiency and reduction of the dispersion grain size are increasing. Therefore, if energies are increased (a round speed and a filling rate are increased), there is such a possibility that even using hard beads, an increase in abrasion and/or generation of heat occurs, thereby raising a problem about quality and the process of production.

As a method of reducing an abrasion material, while increasing productivity, and accomplishing reduction in coarse grains by rendering the grains more fine, an attempt to make the average grain size of the media small has been made. Usually the media and a dispersion are separated from each other by means of a screen, a gap, a slit, a mesh, and so on. In these methods, there are such drawbacks that a material of the separating part tends to be worn out, and the separating part is easily plugged (clogged) as the grain size of the media becomes smaller. Further, especially when a gap is used, a space that is smaller than the grain size of the media must be

maintained, so that both high processing accuracy and control accuracy are required. Accordingly, there is a problem that a large-sized dispersing machine is difficult to manufacture.

- 5 Further, a method of dispersing a material using a polymeric material or fine grains thereof, as the media, followed by separation after dispersion, is also proposed. Such a method is described in, for example, U.S. Patent Nos. 5,500,331, 5,679,138, and 5,662,279, and European
- 10 Patent (EP) Nos. 684508A and 684519A. However, these methods have such drawbacks that both the hardness and density of the media are low, and the dispersion speed is slow, and abrasion of the polymer occurs.

- As a method of preventing beads from clogging, there
- 15 are proposed methods of rotating a screen, or applying thereto vibration, as described in, for example, Utility Model Registration No. 3006047, JP-A-63-65959 ("JP-A" means unexamined published Japanese patent application), JP-A-10-118512, and JP-A-8-252472. These methods are not
- 20 to prevent the media itself from reaching the screen, but an attempt to mechanically reduce the probability that the media becomes plugged even though the media have reached the screen. Consequently, it is difficult to say that the effects obtained thereby are satisfactory.

SUMMARY OF THE INVENTION

An object of the present invention is to provide a method of efficiently preparing a photographic solid fine-grain dispersion, wherein neither coarse grains nor abrasion materials resulting from media or so on exist, and moreover no aggregate occurs during storage, and which dispersion causes no trouble when the same is coated in a form of the coating film. Another object of the present invention is to provide such a dispersion.

10 Still another object of the present invention is to provide a silver halide photographic light-sensitive material using such a dispersion.

Other and further objects, features, and advantages of the invention will appear more fully from the following description, taken in connection with the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 1 is a schematic structural view of a grinder in a dispersing machine of the type, in which an overcap is provided in the vicinity of a screen to impart media centrifugal force, thereby returning the media from a media-separating chamber to a grinding chamber, and in the same time, the media is separated with the screen.

25 Fig. 2 is a schematic structural view of a grinder

in a dispersing machine of the type, in which media is returned by centrifugal force from a media-separating chamber to a grinding chamber, and simultaneously a slurry is taken out through an axial center of the media-separating chamber.

DETAILED DESCRIPTION OF THE INVENTION

As a result of intensive investigation, the present inventors have found that the above-described objects can be accomplished by the following means. That is, according to the present invention, there are provided:

- (1) A method of preparing a photographic solid fine-grain dispersion, the method comprising the steps of:
 - successively bringing a slurry of a water-insoluble photographically useful compound in a grinding chamber of a dispersing machine, which chamber is filled with media, allowing the compound to contact the media in the grinding chamber, to produce fine grains of the compound successively,
 - successively separating the media from the compound by centrifugal force, and
 - taking the compound out of the grinding chamber, wherein the bulk density of the media is 4.0 g/cm^3 or more, the Vickers hardness thereof is 10 GPa or more, the breaking tenacity thereof is $5 \text{ MPa} \cdot \text{m}^{1/2}$ or more, and

the average grain size thereof is 0.3 mm or less;

- (2) The method of preparing a photographic solid fine-grain dispersion as described in the above item (1), wherein the dispersion machine has such a mechanism that
- 5 the same comprises a cylindrical container having a feed port and a discharge port for slurry, a screen covering the discharge port and projecting inward a dispersing container, and a rotatable shaft equipped (installed) with a plurality of stirrers; wherein at the feed port side of
- 10 the cylindrical container, the grinding chamber filled with the media is arranged, and at the discharge port side of the cylindrical container, a media-separating chamber in which substantially no media exist, is arranged, respectively; wherein a disc-like rotor mounted on the
- 15 rotatable shaft at the closest side to the discharge port is equipped with a stirrer member, the tip of which extends to the vicinity of a lateral face at the discharge port side of the screen; wherein, by rotation of the stirrer member, centrifugal force is applied to the media
- 20 introduced into the separating chamber, and thereby the media is returned to the grinding chamber;

- (3) The method of preparing a photographic solid fine-grain dispersion as described in the above item (1), wherein the dispersing machine comprises a grinding
- 25 chamber filled with beads and having a feed port and a

discharge port for slurry, a rotatable shaft equipped with a stirrer, and a media-separating chamber containing substantially no media, which chamber is separated by a wall from the grinding chamber and which chamber is
5 installed with an impeller that applies by rotation a centrifugal force to the media introduced into the separating chamber to return the media to the grinding chamber taking out the slurry through a discharge passage formed in the rotatable shaft;

- 10 (4) The method of preparing a photographic solid fine-grain dispersion as described in any one of the above items (1) to (3), wherein the member that contacts the media of the dispersing machine, is composed of a material selected from a ceramic whose main component is
15 substantially a zirconia or an alumina, a polyurethane, a polytetrafluoroethylene (Teflon, trade name), and a polyethylene;

- (5) A photographic solid fine-grain dispersion, which is obtained by the preparation method as described
20 in any one of the above items (1) to (4);

- (6) The photographic solid fine-grain dispersion as described in the above item (5), wherein the media and/or foreign matters resulting from the dispersing machine are contained in an amount of 100 ppm or less, in terms of the
25 weight ratio in the dispersion;

(7) The photographic solid fine-grain dispersion as described in the above item (5) or (6), wherein the water-insoluble photographically useful compound is a compound represented by general formula (I):

5 General formula (I)

Wherein, in general formula (I), D represents a residue of a compound having a chromophore; X represents a dissociating hydrogen atom, or a group having a
10 dissociating hydrogen atom; and y represents an integer of 1 to 7;

(8) The photographic solid fine-grain dispersion as described in any one of the above items (5) to (7), which further contains a water-soluble synthetic high-molecular
15 compound;

(9) The photographic solid fine-grain dispersion as described in the above item (8), wherein the synthetic high-molecular compound is an anionic high molecule;

(10) The photographic solid fine-grain dispersion
20 as described in the above item (8) or (9), wherein the number-average molecular weight of the high-molecular compound is in the range of 2000 to 12000;

(11) The photographic solid fine-grain dispersion as described in the above item (9) or (10), wherein the
25 high-molecular-weight compound is a compound containing a

recurring (repeating) unit of a monomer represented by
general formula (II):

General formula (II)

10 wherein L represents an aliphatic divalent group
having 1 to 50 carbon atoms, M represents a hydrogen atom
or a monovalent cation, and n represents 0 or 1.

(12) A coating composition for a silver halide
photographic light-sensitive material, which composition
15 comprises the photographic solid fine-grain dispersion as
described in any one of the above items (5) to (11); and

(13) A silver halide photographic light-sensitive
material having at least one light-sensitive silver halide
emulsion layer on a support, which comprises the
20 photographic solid fine-grain dispersion as described in
any one of the above items (5) to (11).

The term "a water-insoluble photographically useful
compound" that can be used in the method of the present
invention, means any kind of organic compounds that are
25 useful for a photographic use, and organic or inorganic

dyestuffs and pigments. Further, the term "water-insoluble" used in the present specification means a situation in which, when a necessary amount of the photographically useful compound is added to a

5 photographic element, the whole amount of the compound cannot be added to the coating solution as an aqueous solution, for lack of solubility, even though the coating solution is diluted to the limiting concentration of the range in which a coating is possible. The water-

10 insolubility means that solubility is generally 10 or less, and preferably 5 or less, to 100 g of water at 20°C.

Examples of the water-insoluble photographically useful compound to which the present invention can be applied, include a dye image-forming coupler, a dye image-

15 providing redox compound, an antistain agent, an antifoggant, an ultraviolet absorber, an antifading agent, a color-mix-preventing agent, a nucleating agent, a silver halide solvent, a bleaching accelerator, a developing agent, a filter dye and a precursor thereof, a dyestuff, a

20 pigment, a sensitizing agent, a hardener, a whitening agent, a desensitizing agent, an antistatic agent, an antioxidant, a developer scavenger, a mordant, a matte agent, a development accelerator, a development inhibitor, a heat solvent, a color-tone modifier, a sliding agent,

25 and a polymer latex for dispersion which is used as a

medium for dispersing thereof, and a water-insoluble inorganic salt (e.g., zinc hydroxide). These compounds are described in, for example, Research Disclosure (R.D.) No. 17643, ibid. No. 18716, and ibid. No. 307105.

5 As a dyestuff or a pigment to which the present invention can be applied, can be mentioned azo-series, azomethine-series, oxonol-series, cyanine-series, phthalocyanine-series, quinacridone-series, anthraquinone-series, dioxazine-series, indigo-series, perynone/
10 perylene-series, titanium oxide, cadmium-series, iron oxide-series, chromium oxide, carbon black organic dyestuffs (pigments) or inorganic dyestuffs (pigments), but not limited thereto. In addition, as a coloring agent, can be applied any of publicly known dyes, which have
15 conventionally been used, or a mixture thereof. In the present invention, these dyestuffs (pigments) can be used in any of the states such as an aqueous paste state just after the preparation, or a powder state. The dyestuffs that can be used in the present invention are preferably
20 those represented by the following general formula (I).
General formula (I)

In general formula (I), D represents a residue of the compound having a chromophore; X represents a
25 dissociating hydrogen atom, or a group having a

dissociating hydrogen atom; and y represents an integer of 1 to 7. The dye represented by general formula (I) for use in the present invention is characterized in that the dye has a dissociating hydrogen atom or so on, in its molecular structure. That the dye has a dissociating hydrogen atom, or a group having a dissociating hydrogen atom in its molecular structure, is preferred from a viewpoint that the dye is decolored and removed at the time of a development processing.

The compound having a chromophore in the group D is not limited in particular, and therefore it can be selected from various kinds of publicly known dyes. Examples of these compounds include oxonol dyes, merocyanine dyes, cyanine dyes, arylidene dyes, azomethine dyes, triphenylmethane dyes, azo dyes, anthraquinone dyes, and indoaniline dyes.

The dissociating hydrogen atom or the group having a dissociating hydrogen atom represented by X, has such characteristics that the atom or group is of non-dissociation in the state when the dyestuff represented by general formula (I) has been added to a silver halide photographic light-sensitive material of the present invention, thereby making the dyestuff of general formula (I) substantially water-insoluble; whereas the atom or group dissociates in the working step when said light-

sensitive material is subjected to development, to make the compound of general formula (I) substantially water-soluble. Examples of the group having a dissociating hydrogen atom represented by X include groups having a

5 carboxylic acid group, a sulfonamide group, a sulfamoyl group, a sulfonylcarbamoyl group, an acylsulfamoyl group, a phenolic hydroxyl group, and so on. Exemplary dissociating hydrogen atom represented by X includes, for example, a hydrogen atom of the enol group in an oxonol

10 dye.

A substituent which each of the above-described groups may have, is not limited in particular, unless the substituent imparts the compound of general formula (I) substantial solubility in water having a pH of 5 to 7.

15 Examples of the substituent include a carboxylic acid group, a sulfonamido group having 1 to 10 carbon atoms (e.g., methanesulfonamido, benzenesulfonamido, butanesulfonamido, n-octanesulfonamido), an unsubstituted, or alkyl- or aryl-substituted sulfamoyl group having 0 to

20 10 carbon atoms (e.g., unsubstituted sulfamoyl, methylsulfamoyl, phenylsulfamoyl, naphthylsulfamoyl, butylsulfamoyl), a sulfonylcarbamoyl group having 2 to 10 carbon atoms (e.g., methanesulfonylcarbamoyl, propanesulfonylcarbamoyl, benzenesulfonylcarbamoyl), an

25 acylsulfamoyl group having 1 to 10 carbon atoms (e.g.,

acetylsulfamoyl, propionysulfamoyl, pivaloylsulfamoyl, benzoylsulfamoyl), a chain or cyclic alkyl group having 1 to 8 carbon atoms (e.g., methyl, ethyl, isopropyl, butyl, hexyl, cyclopropyl, cyclopentyl, cyclohexyl, 2-
5 hydroxyethyl, 4-carboxybutyl, 2-methoxyethyl, benzyl, phenethyl, 4-carboxybenzyl, 2-diethylaminoethyl), an alkenyl group having 2 to 8 carbon atoms (e.g., vinyl, allyl), an alkoxy group having 1 to 8 carbon atoms (e.g., methoxy, ethoxy, butoxy), a halogen atom (e.g., F, Cl, Br),
10 an amino group having 0 to 10 carbon atoms (e.g., unsubstituted amino, dimethylamino, diethylamino, carboxyethylamino), an ester group having 2 to 10 carbon atoms (e.g., methoxycarbonyl), an amido group having 1 to 10 carbon atoms (e.g., acetylamino, benzamido), a
15 carbamoyl group having 1 to 10 carbon atoms (e.g., unsubstituted carbamoyl, methylcarbamoyl, ethylcarbamoyl), an aryl group having 6 to 10 carbon atoms (e.g., phenyl, naphthyl, hydroxyphenyl, 4-carboxyphenyl, 3-carboxyphenyl, 3,5-dicarboxyphenyl, 4-methanesulfonamidophenyl, 4-
20 butanesulfonamidophenyl), an aryloxy group having 6 to 10 carbon atoms (e.g., phenoxy, 4-carboxyphenoxy, 3-methylphenoxy, naphthoxy), an alkylthio group having 1 to 8 carbon atoms (e.g., methylthio, ethylthio, octylthio), an arylthio group having 6 to 10 carbon atoms (e.g.,
25 phenylthio, naphthylthio), an acyl group having 1 to 10

carbon atoms (e.g., acetyl, benzoyl, propanoyl), a sulfonyl group having 1 to 10 carbon atoms (e.g., methanesulfonyl, benzenesulfonyl), a ureido group having 1 to 10 carbon atoms (e.g., ureido, methylureido), a
5 urethane group having 2 to 10 carbon atoms (e.g., methoxycarbonylamino, ethoxycarbonylamino), a cyano group, a hydroxyl group, a nitro group, and a heterocyclic group (e.g., 5-carboxybenzoxazole ring, pyridine ring, sulfolane ring, pyrrole ring, pyrrolidine ring, morpholine ring,
10 piperazine ring, pyrimidine ring, furan ring).

Specific examples of the compounds for use in the method of the present invention are shown below. However, the present invention should not be limited thereto.

As a dispersing machine for use in the present invention, for example, JP-B-2-10699 ("JP-B" means examined Japanese patent publication), JP-A-6-31189, and JU-B-6-41638 ("JU-B" means examined Japanese utility model publication) disclose attempts for reducing an amount of the media that would reach a screen part, which attempts comprises rotating a rotor or a cap mounted around the screen projecting inward a dispersing machine, thereby applying centrifugal force to the media. These are effective to avoid clogging of the screen. However, even though these are used, a large amount of the media still reach the vicinity of the screen.

A further preferable dispersing machine is a machine of the type wherein a grinding chamber in which media exist and pulverizing is carried out therewith, is separated from a media-separating chamber in which the media is separated so that substantially no media exist therein. These two components are characterized in that they are contained in the same dispersing container, in which a barrier (wall) may exist or not, and in that the media entered into the media separating chamber is returned to the grinding chamber by centrifugal force of a stirrer member or an impeller provided in the separating chamber, so that substantially no media exist in the media-separating chamber. These separating machines are

described in, for example, JU-B-6-41638, JU-B-7-46353, and
WO 96/39251.

The method of the present invention can be
preferably practiced by employing the dispersing machine
5 shown in Fig. 1.

Fig. 1 is a sectional view of a dispersing machine.
In the figure, 1 is a grinder (mill) entity, 2 is a
cooling water jacket, and 3 is a dispersion stirrer (a
disk for dispersion in this figure) mounted on a rotatable
10 shaft 4. The stirrer may be a disk, a disk with a pin, an
eccentric disk, a pin, or so on. 7 is a slurry take-in
port (a slurry of a water-insoluble photographically
useful compound). The slurry is introduced into a
grinding chamber 9 filled with media to be finely
15 pulverized by means of the dispersion stirrer 3 and the
media. 8 is a take-out port for the finely ground slurry.
5 is a screen for separating the media, and the screen 5
covers the take-out port 8 for the slurry and it is
projecting inward of a dispersing container. 6 is a
20 stick-like stirrer member (an overcap) fitting to the disk
which is mounted on the shaft 4 at the closest side to an
outlet (discharge port). Further the overcap 6 is located
in a media-separating chamber 10, and it is extending up
to the vicinity of a lateral face at the outlet side of
25 the screen 5, and also it is covering all over the surface

of the screen 5. The stirrer member 6, when rotated, functions so that centrifugal force is applied to the media having entered into the media-separating chamber and the same is returned to the grinding chamber. Therefore, substantially no media exist in the media-separating chamber during dispersion. Accordingly, a screen clogging can be prevented.

The shape of the stirrer member is not limited so long as it functions as described above. For example, a blade-type or basket (cage)-type stirrer may be used.

As an example of the above dispersing machine, there is available AGITATOR MILL LMK, trade name, manufactured by Ashizawa K.K.

Fig. 2 is a sectional view of another example of the dispersing machine for use in the practice of the present invention. In the figure, 11 is a cooling water jacket, 12 is a grinder (mill) entity, 14 is a dispersion stirrer (a pin in this figure) mounted on a rotatable shaft 15. The stirrer may be a disk, a disk with a pin, an eccentric disk, a pin, or so on. 13 is a slurry take-in port, and the slurry is introduced into a grinding chamber 18 filled with media to be finely pulverized by means of the dispersion stirrer 14 and the media. 16 is a media-separating chamber, which is called a sentry separator. In this example, the chamber is composed of two sheets of

disks affixed on the shaft and a blade 20 sandwiched between them. By rotation thereof, the media-separating chamber serves as an impeller, and functions so that centrifugal force is applied to the media having entered
5 into the chamber and the same is returned to the grinding chamber. Therefore, substantially no media exist in the media-separating chamber during dispersion. Finely ground slurry enters from a take-in port (feed port) 19 between the disks, and it is taken out through a slurry-
10 discharging passage 17 provided inside of the shaft, via the sentry separator. The structure of the media-separating chamber is not limited, so long as the chamber has such a function that media having entered therein can be discharged by an impeller. For example, such an
15 embodiment is acceptable that upper and lower disks do not rotate, but an impeller does rotate, which has been provided separately therein.

As an example of such a dispersing machine, there is available SAM, trade name, manufactured by Kotobuki Giken
20 Industry Co., Ltd.

It is preferred that a welding part of the grinding chamber in a dispersing machine for use in the present invention be formed by a material selected from a group consisting of SiC, SiN, and ceramics which contain
25 zirconia or alumina as a main component, with zirconia-

enriched alumina being more preferred.

It is preferred that a stirrer part (e.g., disk, pin) of the dispersion machine for use in the present invention, is made of a material selected from zirconia, or a resin made of a polyurethane, a polytetrafluoroethylene (Teflon, trade name), a polyamide (Nylon, trade name), a polyethylene, a polypropylene, or an ABS.

In the method of the present invention, as the media, there can be used publicly known media for dispersion. The average grain size of the media is preferably in the range of 0.02 mm to 0.3 mm, more preferably in the range of 0.05 mm to 0.2 mm, and furthermore preferably in the range of 0.05 mm to 0.1 mm. It is possible that the grain size reduction not only reduces an excessive collision energy at the time of collision occurring among media, or between the media and the member, but also increases the number of collision, thereby improving a dispersion efficiency.

As the density of media is higher, presumably an impact force becomes larger, and also does a shearing force, and therefore an improvement of the dispersion speed can be expected. As the hardness of media is higher (more harder), assumably an impact force becomes larger, but a breaking tenacity is also an important factor to the

fracture. Therefore, it is preferred that both factors of hardness and breaking tenacity be higher to some extent. As a result of intensive investigations, it has been found to be preferred that the bulk specific gravity of the media is 4.0 g/cm³ or more, the Vickers hardness thereof is 10 GPa or more, and the breaking tenacity thereof is 5 MPa·m^{1/2} or more. The Vickers hardness and the breaking tenacity are defined in JIS R1610 and JIS R1607 respectively.

- 10 Values of these physical properties relating main media are shown in Table 1. Zirconia has a high bulk specific gravity. Alumina has a high hardness, but a low breaking tenacity. Namely, alumina is hard, but fragile. Zircon beads are inferior in both the hardness and
- 15 breaking tenacity. In contrast, zirconia beads are superior to in both of these properties of hardness and tenacity.

Table 1 Physical properties of various beads materials

	Zirconia	ZS	Alumina	Glass	NS	Si ₃ N ₄
Bulk specific gravity (g/cm ³)	5.5-6.1	4.6-3.8	3.9	-3.2	3.2	3.2
Breaking tenacity (Mpa m ^{1/2})	6-7	3-4	2-3	2-3	4-6	2-3
Vickers hardness (GPa)	13-14	7	16-20	-8.8	13-18	25-28

As to a material of the media, zirconia is preferred, and tetragonal polycrystalline zirconia is especially preferred. These materials in which yttria, calcium oxide, magnesium oxide, alumina, or ceria is further doped, are
5 also preferred. Those in which yttria or alumina is doped, are more preferred because they have both high strength and tenacity.

Further, the filling rate of media in the grinding chamber is preferably in the range of 70% to 90%, and more
10 preferably in the range of 75% to 87%. Herein, the filling rate means a ratio of a volume of media having been most densely filled, said volume including a vacant space among the media, to a space volume of the interior of the grinding chamber in a dispersion machine.

15 In a method of the present invention, an amount of the foreign matters resulting from the media in a dispersion, or a dispersing machine, is generally 100 ppm or less, preferably 50 ppm or less, and more preferably 10 ppm or less.

20 As for the water-insoluble photographic solid fine-grain dispersion to which a method of the present invention is applied, a content of the solid fine-grains is preferably in the range of 3 to 60 wt.%, more preferably 20 to 60 wt.%, and furthermore preferably 32 to
25 45 wt.%, and the remainder is water as a dispersion medium.

Preferably these solid fine-grain dispersions are prepared in the presence of a dispersing agent (aid). Examples of conventionally known dispersing agents include anionic dispersing agents, such as an

5 alkylphenoxyethoxyethanesulfonic acid salt, a polyoxyethylene alkylphenylether sulfonic acid salt, an alkylbenzenesulfonic acid salt, an alkyl-naphthalenesulfonic acid salt, an alkylsulfonic acid ester salt, an alkylsulfosuccinic acid salt, sodium

10 oleylmethyltauride, a formaldehyde condensation product of naphthalenesulfonic acid, polyacrylic acid, polymethacrylic acid, a copolymer of maleic acid/acrylic acid, carboxymethylcellulose, and sulfuric acid cellulose; nonionic dispersing agents, such as polyoxyethylenealkyl

15 ether, sorbitan fatty acid ester, polyoxyethylenesorbitan fatty acid ester, and a block polymer of polyalkyleneoxide; cationic dispersing agents; and betain-series dispersing agents.

Further, a solid fine-grain dispersion may be

20 prepared in the coexistence of a hydrophilic colloid, such as a polysaccharide and gelatin, for the purpose of the stabilization and viscosity reduction of the dispersion.

It is preferred in the present invention that a synthetic high-molecular compound be added as a dispersing

25 agent. Exemplary high-molecular compounds include a block

polymer of polyalkylene oxide. Anionic high-molecular compounds are more preferred. Examples thereof include a formaldehyde condensation product of naphthalenesulfonic acid, polyacrylic acid, polymethacrylic acid, a copolymer
 5 of maleic acid/acrylic acid, carboxymethyl cellulose, and sulfuric acid cellulose.

High-molecular compounds represented by formula II shown below are more preferred:

formula II

15 wherein L represents a divalent aliphatic group having 1 to 50 carbon atoms; M represents a hydrogen atom or a monovalent cation; and n represents 0 or 1.

Further, a number-average molecular weight thereof is preferably in the range of 2000 to 12000, and more
 20 preferably in the range of 4000 to 8000.

Generally, as a molecular weight of the dispersing agent is smaller, an adsorption speed becomes higher, and also does a dispersion speed, but desorption is also likely to occur, and therefore aggregation or so on tends
 25 to occur during storage of a dispersion solution. On the

other hand, high-molecular-weight dispersing agents have the advantage that stabilization due to steric repulsion is easily accomplished, but there is a possibility that they cause intertwinement among polymer chains or running
5 dry (exhaustion) aggregate. Further, their adsorption to a new interface (surface) formed during dispersing is slow, and a dispersion speed is slow.

Compounds represented by the formula having an ionic group, a polar group, or a hydrophobic group (hydrophobic
10 polymer main chain, aromatic ring) in their molecules, and having a number-average molecular weight of about 2,000 to about 12,000, have the advantages that a speed of their adsorption to a new interface is high, and also the adsorption is strong, and moreover steric repulsion due to
15 a polymer chain can be expected.

In the case where a dispersion speed is extremely high as in the present invention, the adsorption speed and strength to the interface are especially important.
Improvement of a dispersion speed and aggregation
20 resistance of a dispersion agent for use in the present invention is more outstanding, compared to conventional dispersion methods.

In the present invention, a high-molecular dispersing agent and another low-molecular dispersing
25 agent may be used in combination, or alternatively two or

more kinds of high-molecules or dispersing agents may be used in combination.

These dispersing agents may be used in an amount of generally 2 to 30 wt.%, preferably 5 to 20 wt.%, to a
5 material to be dispersed.

As to an addition time of the dispersing agents (aids), they may be added at any time of before, during and after fine-pulverization so long as they are used in the above-described range.

10 Specific examples of dispersing agents (aids) for use in the present invention are shown below. However, the present invention should not be limited to them.

The pH of the dispersion after fine pulverization is preferably in the range of 4.5 to 8, and preferably the pH is adjusted before, during, or after fine pulverization. Further in order to impart a dispersion stability to the dispersion, a dispersion solution may be subjected to heat treatment before or after fine pulverization.

Further in the present invention, it is also preferred to mix a solid fine-grain dispersion with a hydrophilic colloid solution, to make a dispersion. By this method, sedimentation (precipitation) during storage can be prevented, and the thus-prepared dispersion can be coated onto a support as it is, to prepare a photographic light-sensitive material. As the content of a photographically useful compound in the dispersion is higher, the productivity of manufacture is higher and an equipment for the storage can be miniaturized, and also a drying load at the time of coating can be controlled to a lower level. The above-said content is generally in the range of 3 wt.% to 50 wt.%, preferably 7 wt.% to 30 wt.%, and more preferably 10 wt.% to 25 wt.%.

Of the hydrophilic colloids, gelatin is preferred.

To provide a layer containing fine grains of a dye for a photographic light-sensitive material, there can be used a method comprising the steps of: preparing a solid dispersion of approximately uniform grains by dispersing

the thus-obtained grains into a suitable binder, and then applying the solid dispersion onto a desired support.

The above-described binders are not limited in particular, so long as they are a hydrophilic colloid which can be used for a light-sensitive emulsion layer or a light-insensitive layer. Generally, gelatin, or a synthetic polymer, such as polyvinyl alcohol and polyacrylamide, is used.

Fine grains in the solid dispersion prepared by the method of the present invention preferably have an average grain size of $0.005\text{ }\mu\text{m}$ to $10\text{ }\mu\text{m}$, more preferably $0.01\text{ }\mu\text{m}$ to $1\text{ }\mu\text{m}$, and furthermore preferably $0.02\text{ }\mu\text{m}$ to $0.5\text{ }\mu\text{m}$.

A solid fine-grain dispersion of a dye prepared by the method of the present invention, can be incorporated in a light-insensitive hydrophilic colloid layer according to a hue of the dye in a silver halide photographic light-sensitive material. In the light-sensitive material having an embodiment wherein the above-said light-insensitive layer is composed of plural layers, the above-described solid fine-grain dispersion can be incorporated in each of the plural layers.

Examples of these silver halide light-sensitive materials include an X ray light-sensitive film, a film for printing (e.g. a graphic arts film), a black-and-white negative film, a color negative film, a color reversal

film, a motion picture film, and a color paper.

As various techniques, or inorganic or organic materials, that can also be used for the silver halide photographic light-sensitive material in the present invention, generally those described in the Research Disclosure No. 308119 (1989) can be used. In addition to the above, techniques or inorganic or organic materials that can be used in the silver halide photographic light-sensitive material of the present invention, are described in the below points of Published EP-A-436,938 (A2) and in the below-referred patent publications.

5 The solid fine-grain dispersion obtained by the
method of the present invention contains neither coarse
grains nor abrasion materials resulting from media or so
on, and further the dispersion causes no defect when
coated in a hydrophilic colloid layer of a silver halide
photographic light-sensitive material.

10 Now, the present invention is described in more
detail with reference to the following examples, but the
present invention is not limited thereto.

EXAMPLE

15 Example 1

(Preparation of Solid Fine-Grain Dispersion S-1 to S-18)
Wet cake of Compound IX-1

(containing water in 17.6 wt.%)	2.80 kg
Compound V-12 (31 wt.% aqueous solution)	0.376 kg
20 Antiseptics (A) (7% aqueous solution)	0.011 kg
Water	4.02 kg
Total	7.21 kg

pH = 7.2 (adjusted by sodium hydroxide)

25 A slurry having the above-described composition was

- roughly dispersed agitating by means of Dissolver, and thereafter the dispersed slurry was further dispersed under the conditions described in Table 2, until the absorbance ratio of the dispersion solution described
- 5 below would become 0.4, to obtain Solid fine-grain dispersions S-1 to S-18. However, as for the dispersions S-9, S-10, S-11, and S-12, absorption of the dispersion solution was not measured, but the dispersing process was finished at the same period of dispersing time as in S-7.
- 10 In the preparation of S-14, dispersing was continued until the absorbance ratio would become 0.17. Further, the grain size of dispersed grains in the slurry of solid fine-grains before the dispersion processing was in the range of about 50 to about 100 μm , although the size was
- 15 different depending on the solid fine-grains to be used.

Properties of the thus-obtained solid fine-grain dispersions are shown in Table 3.

S-18 Comparative example*	260	300	300	0.29

* During dispersing, an increase of the inner pressure was observed.

In the dispersion machine, an entire inner wall of the grinding chamber was made of zirconia-enriched alumina, and a disk or pin, or a gap separator, sentry separator, or screen (pore size 0.05 mm) were made of zirconia.

5 (Evaluation of Coating Film Defect)

Gelatin was added to the dispersion, and the resultant mixture was coated on a transparent TAC, and thereafter the number of defects per a definite area was counted.

10 (Determination of Abrasion Material)

Zr and Al in the dispersion solution were determined by ICP emission spectrophotometry, and the amount of foreign matters resulting from the media or the dispersing machine was calculated.

15 (Measurement of Grain Size)

An average grain size of the dispersion was measured by means of Microtrack UPA-HRA (trade name, manufactured by Nikkaki Co. Ltd.).

(Absorption of Dispersion Solution)

20 Each of the dispersion solutions was diluted so that the content of the photographically useful compound would become 16 ppm. Subsequently, the maximum absorbance (A_1) of the diluted dispersion solution at the visible wavelength region, and also a ratio (A_2/A_1) of the
25 absorbance (A_2) at the wavelength 500 nm being longer than

the specific wavelength providing the maximum absorbance, to Al, were measured.

The solid fine-grain dispersion of the present invention had less foreign matters resulting from the media, and it had no defect. Further, according to the present invention, a small size of media can be used, so that further fine-pulverization and reduction of coarse grains are possible. These solid fine-grain dispersions were employed to prepare silver halide photographic light-sensitive materials in the following Examples.

Example 2

(Preparation of Solid Fine-Grain Dispersions T-1 to T-16)

According to a method of Example 1, dispersions of the composition described in Table 4 were dispersed under the conditions described in Table 4, to obtain Solid fine-grain dispersions T-1 to T-16.

(Evaluation of Stability)

Dispersions were allowed to stand at 40°C for 14 days, and thereafter the grain size was measured. The results are shown in Table 5.

X-6 Polyvinyl pyrrolidone Mw=15000

X-7 Dapral GE202 Mw=12500~25000

(A block copolymer of a branched
 carboxylic acid partially esterified)

A high-molecular dispersing agent for use in the present invention not only accelerates a dispersing speed, but also can prevent aggregation from occurring during storage.

- 5 Further, when a high-efficient dispersing according to the present invention is practiced, or a grain size is small, such an effect is remarkable.

Example 3

(Preparation of Sample 301)

- 10 Layers having the below-shown compositions were formed on a cellulose triacetate film support, having a thickness of 127 μm , that had been provided an undercoat, to prepare a multi-layer color light-sensitive material, which was named Sample 301. Each figure represents the
- 15 amount to be added per square meter of the light-sensitive material. In the followings, it should be noted that the effect/function of a specific compound added is not limited to the use as described.

20 First Layer (Halation-prevention layer)

	Dispersion S-12	in terms of III-25	0.28 g
	Gelatin		2.20 g
	Ultraviolet ray absorbent U-1		0.27 g

	Ninth Layer (First green-sensitive emulsion layer)	
	Emulsion F	silver 0.42 g
5	Emulsion G	silver 0.38 g
	Emulsion H	silver 0.32 g
	Silver bromide emulsion of core/shell-type fine grains, whose surfaces were fogged (av. grain diameter: 0.11 μ m)	
		silver 0.08 g
10	Gelatin	1.53 g
	Coupler C-7	0.07 g
	Coupler C-8	0.17 g
	Compound Cpd-B	0.30mg
	Compound Cpd-C	2.00mg
15	Compound Cpd-K	3.0 mg
	Polymer latex P-2	0.02 g
	High-boiling organic solvent Oil-2	0.10 g
	Tenth Layer (Second green-sensitive emulsion layer)	
	Emulsion I	silver 0.16 g
20	Emulsion J	silver 0.34 g
	Gelatin	0.75 g
	Coupler C-4	0.20 g
	Compound Cpd-B	0.03 g
	Polymer latex P-2	0.01 g
25	High-boiling organic solvent Oil-2	0.01 g

Eleventh Layer (Third green-sensitive emulsion layer)

	Emulsion K	silver	0.44 g
	Gelatin		0.91 g
	Coupler C-4		0.34 g
5	Compound Cpd-B		0.06 g
	Polymer latex P-2		0.01 g
	High-boiling organic solvent Oil-2		0.02 g

Twelfth Layer (Yellow filter layer)

	Dispersion S-17	in terms of IX-1	0.24 g
10	Yellow colloidal silver		0.02 g
	Gelatin		0.73 g
	Compound Cpd-G		0.02 g
	Compound Cpd-J		0.04 g
	High-boiling organic solvent Oil-3		0.08 g
15	Polymer M-1		0.23 g

Thirteenth Layer (First blue-sensitive emulsion layer)

	Emulsion L	silver	0.35 g
	Gelatin		0.55 g
	Coupler C-5		0.20 g
20	Coupler C-6		4.00 g
	Coupler C-10		0.02 g
	Compound Cpd-E		0.07 g
	Compound Cpd-K		0.03mg

Fourteenth Layer (Second blue-sensitive emulsion layer)

25	Emulsion M	silver	0.06 g
----	------------	--------	--------

	Emulsion N	silver	0.10 g
	Gelatin		0.75 g
	Coupler C-5		0.35 g
	Coupler C-6		5.00 g
5	Coupler C-10		0.30 g
	Compound Cpd-E		0.04 g
Fifteenth Layer (Third blue-sensitive emulsion layer)			
	Emulsion O	silver	0.20 g
	Emulsion P	silver	0.02 g
10	Gelatin		2.40 g
	Coupler C-6		0.09 g
	Coupler C-10		0.90 g
	Compound Cpd-E		0.09 g
	Compound Cpd-M		0.05mg
15	High-boiling organic solvent Oil-2		0.40 g
	Additive P-2		0.10 g
Sixteenth Layer (First protective layer)			
	Gelatin		1.30 g
	Ultraviolet ray absorber U-1		0.10 g
20	Ultraviolet ray absorber U-2		0.03 g
	Ultraviolet ray absorber U-5		0.20 g
	Compound Cpd-F		0.40 g
	Compound Cpd-J		0.06 g
	Dye D-1		0.01 g
25	Dye D-2		0.01 g

	Dye D-3	0.01 g
	Dye D-5	0.01 g
	High-boiling organic solvent Oil-2	0.37 g
	Seventeenth Layer (Second protective layer)	
5	Silver iodobromide emulsion of fine grains (average grain diameter 0.06 μm , silver iodide content 1 mol%)	silver 0.05 g
	Gelatin	1.80 g
	Compound Cpd-L	0.8 mg
10	Polymethyl methacrylate (average grain diameter 1.5 μm)	5.00 g
	Copolymer of methyl methacrylate and methacrylic acid (6 : 4) (average grain diameter 1.5 μm)	0.10 g
	Silicon oil SO-1	0.030 g
15	Surface active agent W-2	0.030 g
	P-3	0.14 g

Further, to all emulsion layers, in addition to the above-described components, additives F-1 to F-11 were added. Further, to each layer, in addition to the above-described components, gelatin hardener H-1 and surface active agents W-1, W-3, W-4, W-5, and W-6 for coating and emulsifying were added.

Further, as antifungal and antibacterial agents, phenol, 1,2-benzisothiazoline-3-one, 2-phenoxyethanol,

phenethylalcohol, and p-hydroxybenzoic acid butyl ester were added.

The light-sensitive emulsions used for preparation of Sample 301 were shown in Table 6.

- Note 1) Each of emulsions described above was subjected to chemical sensitization using gold/sulfur/selenium.
- Note 2) To each emulsions described above, sensitizing dyes were added prior to chemical sensitization.
- Note 3) To each emulsions described above, compounds F-5, F-7, F-8, F-9, F-10, F-11, F-12, F-13, F-14, and F-15 were added appropriately.
- Note 4) Emulsions described above contain triple structured tabular grains, and the main plane of those grains was a (100) plane for emulsions A, B, I, J and a (111) plane for the other emulsions.
- Note 5) Emulsions A, B, E, F, I, P were emulsions containing grains whose internal sensitivity was higher than its surface sensitivity.
- Note 6) Emulsions described above obtained by making epitaxial growth of silver chloride after chemical sensitization.
- Note 7) In grains of emulsions other than emulsions A, E, F, at least 50 dislocation lines per grain were observed by means of a transmission-type electron microscope.

 10 Compositions of each processing solutions used were as follows:

	[First developer]	Tank solution	Reple- nisher
	Pentasodium nitrilo-		
15	N,N,N-trimethylene- phosphonate	1.5 g	1.5 g
	Pentasodium diethylenetriamine-		
	pentaacetate	2.0 g	2.0 g
20	Sodium sulfite	30 g	30 g
	Hydroquinone/potassium monosulfonate	20 g	20 g
	Potassium carbonate	15 g	20 g
	Sodium bicarbonate	12 g	15 g
25	1-Phenyl-4-methyl-4-		

	hydroxymethyl-3-		
	pyrazolydone	1.5 g	2.0 g
	Potassium bromide	2.5 g	1.4 g
	Potassium thiocyanate	1.2 g	1.2 g
5	Potassium iodide	2.0 mg	-
	Diethylene glycol	13 g	15 g
	Water to make	1,000 ml	1,000 ml
	pH	9.60	9.60
	(pH was adjusted by using sulfuric acid or potassium		
10	hydroxide.)		
	[Reversal solution]	Tank	Reple-
		solution	nisher
	Pentasodium nitrilo-		
	N,N,N-trimethylene-		
15	phosphonate	3.0 g	Same to Tank
	Stannous chloride dihydrate	1.0 g	solution
	p-Aminophenol	0.1 g	
	Sodium hydroxide	8 g	
	Glacial acetic acid	15 ml	
20	Water to make	1,000 ml	
	pH	6.00	
	(pH was adjusted by using acetic acid or sodium		
	hydroxide.)		
	[Color developer]	Tank	Reple-
25		solution	nisher

	Pentasodium nitrilo-		
	N,N,N-trimethylene-		
	phosphonate	2.0 g	2.0 g
	Sodium sulfite	7.0 g	7.0 g
5	Trisodium phosphate		
	12-hydrate	36 g	36 g
	Potassium bromide	1.0 g	-
	Potassium iodide	90 mg	-
	Sodium hydroxide	3.0 g	3.0 g
10	Cytrazinic acid	1.5 g	1.5 g
	N-Ethyl-N-(β -methane-		
	sulfonamidoethyl)-3-methyl-		
	4-aminoaniline-3/2 sulfate-		
	mono hydrate	11 g	11 g
15	3,6-Dithiaoctane-1,8-		
	diol	1.0 g	1.0 g
	Water to make	1,000 ml	1,000 ml
	pH	11.80	11.80
	(pH was adjusted by using acetic acid or potassium		
20	hydroxide.)		
	[Pre-bleaching solution]	Tank	Reple-
		solution	nisher
	Disodium ethylenediamine-		
	tetraacetate dihydrate	8.0 g	8.0 g
25	Sodium sulfite	6.0 g	8.0 g

	1-Thioglycerol	0.4 g	0.4 g
	Formaldehyde-sodium bisulfite adduct	30 g	35 g
	Water to make	1,000 ml	1,000 ml
5	pH	6.30	6.10
	(pH was adjusted by using acetic acid or sodium hydroxide.)		
	[Bleaching solution]	Tank solution	Reple- nisher
10	Disodium ethylenediamine- tetraacetate dihydrate	2.0 g	4.0 g
	Iron (III) ammonium ethylenediaminetetraacetate dihydrate	120 g	240 g
15	Potassium bromide	100 g	200 g
	Ammonium nitrate	10 g	20 g
	Water to make	1,000 ml	1,000 ml
	pH	5.70	5.50
	(pH was adjusted by using nitric acid or sodium hydroxide.)		
20	[Fixing solution]	Tank solution	Reple- nisher
	Ammonium thiosulfate	80 g	Same to tank solution
25	Sodium sulfite	5.0 g	"

	Sodium bisulfite	5.0 g	"
	Water to make	1,000 ml	1,000 ml
	pH	6.60	
	(pH was adjusted by using acetic acid or aqueous ammonia.)		
5	[Stavilizing solution]	Tank solution	Reple-
			nisher
	1,2-benzoisothiazoline-3-one	0.02 g	0.03 g
	Polyoxyethylene-p-monononyl		
10	phenyl ether (av. polymerization degree: 10)	0.3 g	0.3 g
	Polymaleic acid (av. molecular weight: 2000)	0.1 g	0.15 g
	Water to make	1,000 ml	1,000 ml
15	pH	7.0	7.0

It was observed that the sample according to the present invention was excellent in such properties as sensitivity (speed), gradation, sharpness, color balance at the time of push-processing, silver removal characteristics, and pressure-induced sensitization/desensitization. Further, neither defect nor unevenness were found in the sample.

25 Example 4

(Preparation of Sample 401)

1) Support

The support that was used in this example was prepared as follows:

5 100 weight parts of polyethylene-2,6-naphthalate
polymer, and 2 weight parts of Tinuvin P. 326 (trade name,
manufactured by Ciba-Geigy Co.), as an ultraviolet
absorbing agent, were dried, then melted at 300 °C;
subsequently they were extruded through a T-type die, and
10 stretched 3.3 times in the lengthwise direction at 140 °C,
and then 3.3 times in the width direction at 130 °C; and
further they were thermally fixed for 6 seconds at 250 °C,
thereby a PEN film having a thickness of 90 µm was
obtained. To the PEN film, appropriate amounts of a blue
15 dye, a magenta dye, and a yellow dye (I-1, I-4, I-6, I-24,
I-26, I-27, and II-5, as described in Kokai Giho: Kogi No.
94-6023) were added. Further, this film was wound around
a stainless steel core (spool) having a diameter of 20 cm,
and thermal history was imparted thereto at 110 °C for 48
20 hours, to obtain a support having suppressed core-set-curl.

2) Coating of an undercoat layer

After both surfaces of the above support were
subjected to corona discharge, UV discharge, and glow
discharge treatments, each side of the support was coated
25 with an undercoat solution having a composition of 0.1

g/m² of gelatin, 0.01 g/m² of sodium a-sulfo-di-2-ethylhexylsuccinate, 0.04 g/m² of salicylic acid, 0.2 g/m² of p-chlorophenol, 0.012 g/m² of (CH₂=CHSO₂CH₂CH₂NHCO)₂CH₂, and 0.02 g/m² of polyamide-epichlorohydrin

5 polycondensation product (10 cc/m², a bar coater was used). The undercoat layer was provided on the side that was heated at a higher temperature at the time of stretching. Drying was carried out at 115 °C for 6 minutes (the roller and the transportation apparatus in the drying zone all

10 were set at 115 °C).

3) Coating of a backing layer

An antistatic layer, a magnetic recording layer, and a slipping layer, each having the compositions mentioned below, were coated on one side of the above support coated

15 with the undercoat layer, as a backing layer.

3-1) Coating of an antistatic layer

0.2 g/m² of a dispersion of fine grain powder of a composite of stannic oxide-antimony oxide having an average grain diameter of 0.005 μm, and the specific

20 resistance of 5 Ω·cm (secondary aggregation grain diameter of about 0.08 μm) was coated with 0.05 g/m² of gelatin, 0.02 g/m² of (CH₂=CHSO₂CH₂CH₂NHCO)₂CH₂, 0.005 g/m² of poly(polymerization degree: 10)oxyethylene-p-nonylphenol, and resorsine.

25 3-2) Coating of a magnetic recording layer

3-Poly(polymerization degree: 15)oxyethylene-propyloxytrimethoxysilan (15 weight%)-coated Co- γ -iron oxide (specific surface area, 43 m²/g; major axis, 0.14 μ m; minor axis, 0.03 μ m; saturation magnetization, 89 emu/g, Fe²⁺/Fe³⁺ = 6/94; the surface was treated with 2 weight% respectively, based on iron oxide, of aluminum oxide and silicon oxide) (0.06 g/m²), diacetylcellulose (dispersion of the iron oxide was carried out by an open kneader and a sand mill) (12 g/m²), and C₂H₅C(CH₃)OCONH-C₆H₃(CH₃)NCO)₃ (0.3 g/m²), as a hardner, were coated using acetone, methylethylketone, and cyclohexanone, as solvents, by means of a bar coater, to obtain a magnetic recording layer having a thickness of 1.2 μ m. Silica grains (0.3 μ m), as a matting agent, and 3-poly(polymerization degree: 15)oxyethylene-propyloxytrimethoxysilan (15 weight%)-coated aluminum oxide (0.15 μ m), as an abrasive, were each added thereto, to give a coverage of 10 mg/m². Drying was conducted at 115 °C for 6 min (the roller and the transportation apparatus in the drying zone all were set at 115 °C). The increment of the color density of D^B of the magnetic recording layer was about 0.1 when X-light (blue filter) was used. The saturation magnetization moment of the magnetic recording layer was 4.2 emu/g, the coercive force was 7.3 x 10⁴ A/m, and the squareness ratio was 65%.

3-3) Preparation of a slipping layer

Diacetyl cellulose (25 mg/m^2), and a mixture of $\text{C}_6\text{H}_{13}\text{CH}(\text{OH})\text{C}_{10}\text{H}_{20}\text{COOC}_{40}\text{H}_{81}$ (Compound a, 6 mg/m^2) and $\text{C}_{50}\text{H}_{101}\text{O}(\text{CH}_2\text{CH}_2\text{O})_{16}\text{H}$ (Compound b, 9 mg/m^2) were coated.

- 5 When adding the mixture, the mixture was dissolved in a solution of xylene and propyleneglycol monomethylether (1/1) at 105°C , and this solution was poured into a 10-fold volume of propyleneglycol monomethylether (normal temperature) and finely dispersed. This was further
- 10 dispersed in acetone, and the obtained dispersion (average grain diameter: $0.01 \mu\text{m}$) was added to the coating solution. Silica grains ($0.3 \mu\text{m}$), as a matting agent, and 3-poly(polymerization degree, 15)oxyethylene-propyloxytrimethoxysilan (15 weight%)-coated aluminum
- 15 oxide ($0.15 \mu\text{m}$), as an abrasive, were each added thereto, to give a coverage of 15 mg/m^2 , respectively. The slipping layer was dried at 115°C for 6 minutes (the roller and the transportation apparatus in the drying zone all were set at 115°C). The slipping layer showed
- 20 excellent performances of the coefficient of dynamic friction: 0.06 (a stainless steel hard ball of $5 \text{ mm}\phi$, diameter, load: 100 g, speed: 6 cm/min), and of the static friction coefficient: 0.07 (clip method). The sliding property of the slipping layer with the emulsion surface,
- 25 which will be described below, was also excellent, such

that the coefficient of dynamic friction was 0.12.

4) Coating of light-sensitive layers

- Layers having the below-shown compositions were multi-coated on the support of the opposite side of the
- 5 backing layer of the support, to prepare a multi-layer color light-sensitive material, Sample 401.

(Compositions of Light-sensitive Layers)

Main materials used in each layer were classified as follows:

- 10 ExC: Cyan coupler UV: Ultraviolet ray absorbent
ExM: Magenta coupler HBS: High-boiling organic solvent
ExY: Yellow coupler H': Gelatin hardening agent
ExS: Sensitizing dye

- Figures corresponding to each component represents
- 15 the coating amount in terms of g/m^2 , and for silver halide, in terms of silver. With respect to sensitizing dyes, the coating amount is shown in mol, per mol of the silver halide in the same layer.

In Table 7,

- (1) Emulsions J' to M' were subjected to reduction sensitization using thiourea dioxide and thiosulfonic acid at the time of preparation of grains, according to the example described in JP-A-2-191938.
- (2) Emulsions C' to E', G' to I', and M' were subjected to gold sensitization, sulfur sensitization and selenium sensitization under the presence of respective spectral sensitizing dyes described for each layer and sodium thiocyanate, according to the example described in JP-A-3-237450.
- (3) At the preparation of tabular grains, low-molecular-weight gelatin was used, according to the example described in JP-A-1-158426.
- (4) In tabular grains, were observed dislocation lines by a high-pressure electron microscope, as described in JP-A-3-237450.
- (5) Emulsions A' to E', G', H', J' to M' contained Rh, Ir, and Fe, each in an optimum amount. Further, the tabulability of tabular silver halide grains is the value defined as Dc/t^2 , wherein Dc is the average diameter of a circle having the same area as the projected area of each tabular grains (which is also referred to as the average circle-equivalent diameter) and t is the average thickness of the tabular grains.

The thus-prepared light-sensitive material was cut into a strip having a length of 160 cm and a width of 24 mm. Two perforations of 2 mm square were made at intervals of 5.8 mm, located at the position of 0.7 mm in the width direction and at one side in the lengthwise direction of the light-sensitive material, respectively. Further, sets of such two perforations were made at intervals of 32 mm. The sample was encased in a plastic film cartridge (patrone, cassette), as illustrated in Fig. 1 to Fig. 7 of the above-described explanation.

FM signals were recorded at the 1,000/s conveying speed between the above-described perforations of the sample light-sensitive material, by means of a head which had a head gap of 5 μ m from the magnetic recording layer-coated surface side of the sample, and which was capable for input and output of the turn number of 2,000.

The recorded samples were stored at 25°C, 55% relative humidity, for 3 days, and thereafter they were evaluated for the following properties.

(1) Photographic property (Sensitivity)

Samples were cut into a desired length, and they were subjected to exposure of a given light amount of white light for 1/100 sec. using a wedge for sensitometry, followed by a color-development processing. As a result, it was observed that the sample according to the present

invention was excellent in sensitivity, graininess (granularity), and color reproduction. Further, the change in these photographic properties at the time of storage was small.

5

Processing				
Processing	time	temperature	Reple-	Tank
step			nisher*	Volume
Color developing	3 min 5 sec	38.0°C	20 ml	17 liters
Bleaching	50 sec	38.0°C	5 ml	5 liters
Fixing (1)	50 sec	38.0°C	-	5 liters
15 Fixing (2)	50 sec	38.0°C	8 ml	5 liters
Washing	30 sec	38.0°C	17 ml	3.5 liters
Stabilizing (1)	20 sec	38.0°C	-	3 liters
Stabilizing (2)	20 sec	38.0°C	15 ml	3 liters
Drying	1 min 30 sec	60°C		

20

Note: * Replenisher amount (ml) per 1.1 m of light-sensitive material of a 35-mm width (corresponding to one 24-Ex. film).

25

Stabilizing was carried out in a countercurrent mode

from tank (2) to tank (1), and overflow solutions from washing were all introduced into fixing bath (2). Further, with respect to the fixing solutions, both tanks were connected by way of countercurrent piping from tank (2) to tank (1). In addition, the carried over amount of color developer to the bleaching step, the carried over amount of bleaching solution to the fixing step, and the carried over amount of fixing solution to the washing step, were, respectively, 2.5 ml, 2.0 ml, and 2.0 ml, per 1.1 m of the light-sensitive material of a 35-mm width. Each crossover time was 6 sec and it was included in the processing time of the preceding step.

Each opening area in the processor were 100 cm² for the color-developer, 120 cm² for the bleaching solution, and about 100 cm² for other processing solutions, respectively.

The composition of each processing solution was as follows, respectively:

20 (Color-developer)	Tank solution	Reple- nisher
	(g)	(g)
Diethylenetriaminepentaacetic acid	2.0	2.0
1-Hydroxyethylidene-1,1-		
25 diphosphonic acid	2.0	2.0

	Sodium sulfite	3.9	5.3
	Potassium carbonate	37.5	39.0
	Potassium bromide	1.4	0.4
	Potassium iodide	1.3 mg	-
5	Disodium-N,N-bis(sulfonatoethyl) hydroxylamine	2.0	2.0
	Hydroxylamine sulfate	2.4	3.3
	2-Methyl-4-[N-ethyl-N-(β -hydroxyethyl) amino]-aniline sulfonate	4.5	6.4
10	Water to make	1.0 liter	1.0 liter
	pH	10.05	10.18
	(pH was adjusted by potassium hydroxide and sulfuric acid.)		
15	(Bleaching solution)	Tank solution	Reple- nisher
		(g)	(g)
	1,3-Diaminopropanetetraacetic acid		
	iron (III) ammonium monohydrate	118	180
20	Ammonium bromide	80	115
	Ammonium nitrate	14	21
	Succinic acid	40	60
	Maleic acid	33	50
	Water to make	1.0 liter	1.0 liter
25	pH	4.4	4.0

(pH was adjusted by aqueous ammonia.)

	(Fixing solution)	Tank	Reple-
		solution	nisher
5		(g)	(g)
	Ammonium methanesulfinate	10	30
	Ammonium methanethiosulfonate	4	12
	Aqueous ammonium thiosulfate solution		
	(700 g/liter)	280 ml	840 ml
10	Imidazole	7	20
	Ethylenediaminetetraacetic acid	15	45
	Water to make	1.0 liter	1.0 liter
	pH	7.4	7.45
	(pH was adjusted by aqueous ammonia and acetic acid)		

15

(Washing water)

Tap water was treated by passage through a mixed bed ion-exchange column filled with an H-type strong acidic cation exchange resin (Amberlite IR-120B, trade name, made by Rohm & Haas) and an OH-type strong basic anion exchange resin (Amberlite IR-400, the same as the above) so that the concentrations of Ca ions and Mg ions in water were both made to decrease to 3 mg/liter or below,

20 followed by adding 20 mg/liter of sodium

25

dichlorinated isocyanurate and 150 mg/liter of sodium sulfate. The pH of this water was in the range of 6.5 to 7.5.

5 (Stabilizing solution)

	(Both tank solution and replenisher)	(g)
	Sodium p-toluenesulfinate	0.03
	Polyoxyethylene-p-monononylphenylether	
	(av. polymerization degree: 10)	0.2
10	Disodium ethylenediaminetetraacetate	0.05
	1,2,4-Triazole	1.3
	1,4-Bis(1,2,4-triazole-1-ylmethyl)pyperazine	0.75
	1,2-Benzoisothiazoline-3-one	0.10
	Water to make	1.0 liter
15	pH	8.5

Example 5

(Preparation of Sample 501)

The support used in this example was prepared in the same manner as in the preparation of the sample in the above Example 4, which support was provided the undercoat layer and the backing layer on the PEN base.

Layers having the below-shown compositions were multi-coated on the support of the opposite side of the backing layer of the support, to prepare a multi-layer

color light-sensitive material, Sample 501.

(Compositions of Light-sensitive Layers)

Main materials used in each layer were classified as follows:

- 5 ExC': Cyan coupler UV': Ultraviolet ray absorbent
 ExM': Magenta coupler HBS': High-boiling organic solvent
 ExY': Yellow coupler H': Gelatin hardening agent
 ExS': Sensitizing dye

- 10 Figures corresponding to each component represents
 the coating amount in terms of g/m^2 , and for silver halide,
 in terms of silver. With respect to sensitizing dyes, the
 coating amount is shown in mol, per mol of the silver
 halide in the same layer.

(Sample 501)

Further, in order to improve preservability,

5 processability, pressure resistance, antimold and antibacterial properties, antistatic property, and coating property, compounds of W"-1 to W"-5, B"-4 to B"-6, and F"-1 to F"-18, and salts of iron, lead, gold, platinum, palladium, iridium, rutheniumu, and rhodium were

10 appropriately added in each layer. Also, 8.5×10^{-3} g of calcium per mol of the silver halide in the coating solution for the eighth layer, and 7.9×10^{-3} g of calcium per mol of the silver halide in the eleventh layer, were added in the form of an aqueous calcium nitrate solution,

15 thereby the sample was prepared.

The AgI content, the grain size, the surface iodide content (percentage), and so on of the emulsions indicated by the above-described abbreviations, are shown in the following Table 8. The surface iodide content can be

20 determined by XPS as described below. Namely, the samples were cooled to -115°C in a vacuum of 1×10 torr or below, and then MgK α as a probe X ray was irradiated to the cooled samples at X ray source voltage of 8 kV and X ray electric current of 20 mA, and thereafter a measurement

25 was carried out with respect to Ag 3d5/2, Br 3d, and I

3d5/2 electrons. An integral intensity of the measured peak was corrected with a sensitivity factor. The surface iodide content was determined, based on these intensity ratio.

Table 8

Emulsion name	Average iodine content (MOL%)	Deviation coefficient concerning distribution of iodine among grains	Average grain diameter (sphere-equivalent diameter; μm)	Deviation coefficient of diameter corresponding to sphere(%)	Diameter of projected area assumed to be a circle (μm)	Ratio of diameter/thickness	Surface iodine content (MOL%)	Grain sharp

In Table 8,

(1) Emulsions L" to O" were subjected to reduction sensitization using thiourea dioxide and thiosulfonic acid at the time of preparation of grains, according to the

5 example described in JP-A-2-191938.

(2) Emulsions A" to O" were subjected to gold sensitization, sulfur sensitization and selenium sensitization, in the presence of respective spectral sensitizing dyes as described for each light-sensitive

10 layer and sodium thiocyanate, according to the example described in JP-A-3-237450.

(3) At the preparation of tabular grains, low-molecular-weight gelatin was used, according to the example described in JP-A-1-158426.

15 (4) In tabular grains, there were observed dislocation lines by a high-pressure electron microscope, as described in JP-A-3-237450.

The above Sample 501 employing a dispersion of the
 25 present invention was excellent in sensitivity,

granularity and sharpness. Further, no surface defect was observed in the sample 501.

Example 6

In Example 1 described in JP-A-9-222694, a dispersion of S-10 was employed in place of the dispersion of dye C. As a result, a desired preferable crossover-cut property was obtained in the resultant sample.

Example 7

In Example 1, Compound C-10 was employed in place of IX-1 of the dispersion S-16, and the resulting mixture was dispersed in the same manner as in Example 1, to obtain Dispersion S-19. In Sample 301 of Example 3, C-10 was coated in the form of the dispersion S-19 as for the layer in which C-10 was employed, to thereby prepare Sample 701. As a result, no surface defect was observed, and the image quality was excellent in the sample 701.

Having described our invention as related to the present embodiments, it is our intention that the invention not be limited by any of the details of the description, unless otherwise specified, but rather be construed broadly within its spirit and scope as set out in the accompanying claims.

WHAT WE CLAIM IS:

1. A method of preparing a photographic solid fine-grain dispersion, the method comprising the steps of:

5 successively bringing a slurry of a water-insoluble photographically useful compound in a grinding chamber of a dispersing machine, which chamber is filled with media,

allowing the compound to contact the media in the grinding chamber, to produce fine grains of the compound
10 successively,

successively separating the media from the compound by centrifugal force, and

taking the compound out of the grinding chamber,

wherein the bulk density of the media is 4.0 g/cm^3
15 or more, the Vickers hardness thereof is 10 GPa or more, the breaking tenacity thereof is $5 \text{ MPa} \cdot \text{m}^{1/2}$ or more, and the average grain size thereof is 0.3 μm or less.

2. The method of preparing a photographic solid
20 fine-grain dispersion as claimed in claim 1, wherein the member that contacts the media of the dispersing machine, is composed of a material selected from a ceramic whose main component is substantially a zirconia or an alumina, a polyurethane, a polytetrafluoroethylene, and a
25 polyethylene.

3. The method of preparing a photographic solid fine-grain dispersion as claimed in claim 1, wherein the dispersion machine has such a mechanism that the same
5 comprises a cylindrical container having a feed port and a discharge port for slurry, a screen covering the discharge port and projecting inward a dispersing container, and a rotatable shaft equipped with a plurality of stirrers; wherein at the feed port side of the cylindrical container,
10 the grinding chamber filled with the media is arranged, and at the discharge port side of the cylindrical container, a media-separating chamber in which substantially no media exist, is arranged, respectively; wherein a disc-like rotor mounted on the rotatable shaft
15 at the closest side to the discharge port is equipped with a stirrer member, the tip of which extends to the vicinity of a lateral face at the discharge port side of the screen; wherein, by rotation of the stirrer member, centrifugal force is applied to the media introduced into
20 the separating chamber, and thereby the media is returned to the grinding chamber.

4. The method of preparing a photographic solid fine-grain dispersion as claimed in claim 3, wherein the
25 member that contacts the media of the dispersing machine,

is composed of a material selected from a ceramic whose main component is substantially a zirconia or an alumina, a polyurethane, a polytetrafluoroethylene, and a polyethylene.

5

5. The method of preparing a photographic solid fine-grain dispersion as claimed in claim 1, wherein the dispersing machine comprises a grinding chamber filled with beads and having a feed port and a discharge port for
10 slurry, a rotatable shaft equipped with an stirrer, and a media-separating chamber containing substantially no media, which chamber is separated by a wall from the grinding chamber and which chamber is installed with an impeller that applies by rotation a centrifugal force to the media
15 introduced into the separating chamber to return the media to the grinding chamber taking out the slurry through a discharge passage formed in the rotatable shaft.

6. The method of preparing a photographic solid
20 fine-grain dispersion as claimed in claim 5, wherein the member that contacts the media of the dispersing machine, is composed of a material selected from a ceramic whose main component is substantially a zirconia or an alumina, a polyurethane, a polytetrafluoroethylene, and a
25 polyethylene.

7. A photographic solid fine-grain dispersion, which is obtained by a preparation method comprising the steps of:

5 successively bringing a slurry of a water-insoluble photographically useful compound in a grinding chamber of a dispersing machine, which chamber is filled with media,

allowing the compound to contact the media in the grinding chamber, to produce fine grains of the compound
10 successively,

successively separating the media from the compound by centrifugal force, and

taking the compound out of the grinding chamber,
wherein the bulk density of the media is 4.0 g/cm^3
15 or more, the Vickers hardness thereof is 10 GPa or more, the breaking tenacity thereof is $5 \text{ MPa} \cdot \text{m}^{1/2}$ or more, and the average grain size thereof is 0.3 μm or less.

8. The photographic solid fine-grain dispersion as
20 claimed in claim 7, wherein, in the preparation method, the dispersion machine has such a mechanism that the same comprises a cylindrical container having a feed port and a discharge port for slurry, a screen covering the discharge port and projecting inward a dispersing container, and a
25 rotatable shaft equipped with a plurality of stirrers;

wherein at the feed port side of the cylindrical container, the grinding chamber filled with the media is arranged, and at the discharge port side of the cylindrical container, a media-separating chamber in which

- 5 substantially no media exist, is arranged, respectively; wherein a disc-like rotor mounted on the rotatable shaft at the closest side to the discharge port is equipped with a stirrer member, the tip of which extends to the vicinity of a lateral face at the discharge port side of the
- 10 screen; wherein, by rotation of the stirrer member, centrifugal force is applied to the media introduced into the separating chamber, and thereby the media is returned to the grinding chamber.

- 15 9. The photographic solid fine-grain dispersion as claimed in claim 7, wherein, in the preparation method, the dispersing machine comprises a grinding chamber filled with beads and having a feed port and a discharge port for slurry, a rotatable shaft equipped with an stirrer, and a
- 20 media-separating chamber containing substantially no media, which chamber is separated by a wall from the grinding chamber and which chamber is installed with an impeller that applies by rotation a centrifugal force to the media introduced into the separating chamber to return the media
- 25 to the grinding chamber taking out the slurry through a

discharge passage formed in the rotatable shaft.

10. The photographic solid fine-grain dispersion as claimed in claim 7, wherein, in the preparation method,
5 the member that contacts the media of the dispersing machine, is composed of a material selected from a ceramic whose main component is substantially a zirconia or an alumina, a polyurethane, a polytetrafluoroethylene, and a polyethylene.

11. The photographic solid fine-grain dispersion as claimed in claim 7, wherein the media and/or foreign
10 matters resulting from the dispersing machine are contained in an amount of 100 ppm or less, in terms of the
15 weight ratio in the dispersion.

12. The photographic solid fine-grain dispersion as claimed in claim 7, wherein the water-insoluble
photographically useful compound is a compound represented
20 by general formula (I):

General formula (I)

wherein D represents a residue of a compound having a chromophore; X represents a dissociating hydrogen atom,
25 or a group having a dissociating hydrogen atom; and y

represents an integer of 1 to 7.

13. The photographic solid fine-grain dispersion as
claimed in claim 7, which further contains a water-soluble
5 synthetic high-molecular compound.

14. The photographic solid fine-grain dispersion as
claimed in claim 13, wherein the synthetic high-molecular
compound is an anionic high molecule.

10

15. The photographic solid fine-grain dispersion as
claimed in claim 14, wherein the number-average molecular
weight of the high-molecular compound is in the range of
2000 to 12000.

15

16. The photographic solid fine-grain dispersion as
claimed in claim 15, wherein the high-molecular-weight
compound is a compound containing a recurring unit of a
monomer represented by general formula (II):

20 General formula (II)

wherein L represents an aliphatic divalent group having 1 to 50 carbon atoms, M represents a hydrogen atom or a monovalent cation, and n represents 0 or 1.

5 17. A coating composition for a silver halide photographic light-sensitive material, which composition comprises a photographic solid fine-grain dispersion that is obtained by a preparation method comprising the steps of:

10 successively bringing a slurry of a water-insoluble photographically useful compound in a grinding chamber of a dispersing machine, which chamber is filled with media,

 allowing the compound to contact the media in the grinding chamber, to produce fine grains of the compound
15 successively,

 successively separating the media from the compound by centrifugal force, and

 taking the compound out of the grinding chamber,

 wherein the bulk density of the media is 4.0 g/cm^3
20 or more, the Vickers hardness thereof is 10 GPa or more, the breaking tenacity thereof is $5 \text{ MPa} \cdot \text{m}^{1/2}$ or more, and the average grain size thereof is 0.3 μm or less.

 18. The coating composition as claimed in claim 17,
25 wherein, in the preparation method, the dispersion machine

has such a mechanism that the same comprises a cylindrical container having a feed port and a discharge port for slurry, a screen covering the discharge port and projecting inward a dispersing container, and a rotatable shaft equipped with a plurality of stirrers; wherein at the feed port side of the cylindrical container, the grinding chamber filled with the media is arranged, and at the discharge port side of the cylindrical container, a media-separating chamber in which substantially no media exist, is arranged, respectively; wherein a disc-like rotor mounted on the rotatable shaft at the closest side to the discharge port is equipped with a stirrer member, the tip of which extends to the vicinity of a lateral face at the discharge port side of the screen; wherein, by rotation of the stirrer member, centrifugal force is applied to the media introduced into the separating chamber, and thereby the media is returned to the grinding chamber.

19. The coating composition as claimed in claim 17, wherein, in the preparation method, the dispersing machine comprises a grinding chamber filled with beads and having a feed port and a discharge port for slurry, a rotatable shaft equipped with an stirrer, and a media-separating chamber containing substantially no media, which chamber

is separated by a wall from the grinding chamber and which chamber is installed with an impeller that applies by rotation a centrifugal force to the media introduced into the separating chamber to return the media to the grinding chamber taking out the slurry through a discharge passage formed in the rotatable shaft.

20. The coating composition as claimed in claim 17, wherein, in the preparation method, the member that contacts the media of the dispersing machine, is composed of a material selected from a ceramic whose main component is substantially a zirconia or an alumina, a polyurethane, a polytetrafluoroethylene, and a polyethylene.

21. The coating composition as claimed in claim 17, wherein the water-insoluble photographically useful compound is a compound represented by general formula (I):
General formula (I)

wherein D represents a residue of a compound having a chromophore; X represents a dissociating hydrogen atom, or a group having a dissociating hydrogen atom; and y represents an integer of 1 to 7.

22. The coating composition as claimed in claim 17,

wherein the photographic solid fine-grain dispersion further contains a water-soluble synthetic high-molecular compound that is an anionic high molecule.

- 5 23. The coating composition as claimed in claim 22, wherein the high-molecular-weight compound is a compound containing a recurring unit of a monomer represented by general formula (II):
General formula (II)

wherein L represents an aliphatic divalent group having 1 to 50 carbon atoms, M represents a hydrogen atom or a monovalent cation, and n represents 0 or 1.

- 20 24. A silver halide photographic light-sensitive material having at least one light-sensitive silver halide emulsion layer on a support, which comprises a photographic solid fine-grain dispersion which is obtained by a preparation method comprising the steps of:
25 successively bringing a slurry of a water-insoluble

photographically useful compound in a grinding chamber of a dispersing machine, which chamber is filled with media, allowing the compound to contact the media in the grinding chamber, to produce fine grains of the compound

5 successively,

successively separating the media from the compound by centrifugal force, and

taking the compound out of the grinding chamber,

wherein the bulk density of the media is 4.0 g/cm^3
10 or more, the Vickers hardness thereof is 10 GPa or more, the breaking tenacity thereof is $5 \text{ MPa} \cdot \text{m}^{1/2}$ or more, and the average grain size thereof is 0.3 μm or less.

25. The silver halide photographic light-sensitive
15 material as claimed in claim 24, wherein, in the preparation method, the dispersion machine has such a mechanism that the same comprises a cylindrical container having a feed port and a discharge port for slurry, a screen covering the discharge port and projecting inward a
20 dispersing container, and a rotatable shaft equipped with a plurality of stirrers; wherein at the feed port side of the cylindrical container, the grinding chamber filled with the media is arranged, and at the discharge port side of the cylindrical container, a media-separating chamber
25 in which substantially no media exist, is arranged,

respectively; wherein a disc-like rotor mounted on the rotatable shaft at the closest side to the discharge port is equipped with a stirrer member, the tip of which extends to the vicinity of a lateral face at the discharge port side of the screen; wherein, by rotation of the stirrer member, centrifugal force is applied to the media introduced into the separating chamber, and thereby the media is returned to the grinding chamber.

10 26. The silver halide photographic light-sensitive material as claimed in claim 24, wherein, in the preparation method, the dispersing machine comprises a grinding chamber filled with beads and having a feed port and a discharge port for slurry, a rotatable shaft
15 equipped with an stirrer, and a media-separating chamber containing substantially no media, which chamber is separated by a wall from the grinding chamber and which chamber is installed with an impeller that applies by rotation a centrifugal force to the media introduced into
20 the separating chamber to return the media to the grinding chamber taking out the slurry through a discharge passage formed in the rotatable shaft.

25 27. The silver halide photographic light-sensitive material as claimed in claim 24, wherein, in the

preparation method, the member that contacts the media of the dispersing machine, is composed of a material selected from a ceramic whose main component is substantially a zirconia or an alumina, a polyurethane, a
5 polytetrafluoroethylene, and a polyethylene.

28. The silver halide photographic light-sensitive material as claimed in claim 24, wherein the water-insoluble photographically useful compound is a compound
10 represented by general formula (I):

General formula (I)

wherein D represents a residue of a compound having a chromophore; X represents a dissociating hydrogen atom,
15 or a group having a dissociating hydrogen atom; and y represents an integer of 1 to 7.

29. The silver halide photographic light-sensitive material as claimed in claim 24, wherein the photographic
20 solid fine-grain dispersion further contains a water-soluble synthetic high-molecular compound that is an anionic high molecule.

30. The silver halide photographic light-sensitive
25 material as claimed in claim 29, wherein the high-

molecular-weight compound is a compound containing a recurring unit of a monomer represented by general formula (II):

General formula (II)

wherein L represents an aliphatic divalent group having 1 to 50 carbon atoms, M represents a hydrogen atom or a monovalent cation, and n represents 0 or 1.

ABSTRACT OF THE DISCLOSURE

PHOTOGRAPHIC SOLID FINE-GRAIN DISPERSION,
METHOD FOR PREPARING THE SAME, AND SILVER HALIDE
5 PHOTOGRAPHIC LIGHT-SENSITIVE MATERIAL

There is disclosed a method of preparing a photographic solid fine-grain dispersion, the method comprising the steps of: successively bringing a slurry of
10 a water-insoluble photographically useful compound in a grinding chamber of a dispersing machine, which chamber is filled with media, allowing the compound to contact the media in the grinding chamber, to produce fine grains of the compound successively, successively separating the
15 media from the compound by centrifugal force, and taking the compound out of the grinding chamber, using specific media with given physical properties. There is also disclosed a dispersion obtained by the method. According to the method, the photographic solid fine-grain
20 dispersion is prepared efficiently, without coarse grains or abrasion materials resulting from media or so, and the dispersion causes no defect when coated in a form of a coating film.
